1 Theory

1.1 Nomenclature

- r := satellite radial distance attracting body
- u := radial velocity
- v := tangential speed
- m := satellite mass
- $\frac{\partial m}{\partial t} = \dot{m} = -\frac{T}{g_0 \cdot I_{sp}} := \text{dm motor mass flow}$
- ϕ := angle of thrust direction with r
- μ := gravitational constant of the attracting body
- θ := the angle formed by r with $r(0)$

1.2 Conditions initiales et finales:

$$\begin{aligned} r(0) &= r_0, & u(0) &= 0, & v(0) &= \sqrt{\frac{\mu}{r_0}} \\ r(t_f) &= r_f, & u(t_f) &= 0, & v(t_f) &= \sqrt{\frac{\mu}{r_f}} \end{aligned}$$

1.3 Hamiltonien et dynamique de l'état adjoint:

$$\dot{x} = \begin{bmatrix} \dot{r} \\ \dot{u} \\ \dot{v} \end{bmatrix} = f(x, t, \phi) = \begin{bmatrix} u \\ \frac{v^2}{r} - \frac{\mu}{r^2} + \frac{T}{m_0 + \dot{m} \times t} \sin(\phi) \\ -\frac{uv}{r} + \frac{T}{m_0 + \dot{m} \times t} \cos(\phi) \end{bmatrix}$$

$$\lambda^T = [\lambda_r \quad \lambda_u \quad \lambda_v]$$

$$H = 1 + \lambda^T f = 1 + \lambda_r u + \lambda_u \left(\frac{v^2}{r} - \frac{\mu}{r^2} + \frac{T}{m_0 + \dot{m} \times t} \sin(\phi) \right) + \lambda_v \left(-\frac{uv}{r} + \frac{T}{m_0 + \dot{m} \times t} \cos(\phi) \right)$$

$$\dot{\lambda} = \begin{bmatrix} \dot{\lambda}_r \\ \dot{\lambda}_u \\ \dot{\lambda}_v \end{bmatrix} = -\frac{\partial f^T}{\partial x} \lambda = \begin{bmatrix} -\lambda_u \left(-\frac{v^2}{r^2} + \frac{2\mu}{r^3} \right) - \lambda_v \left(\frac{uv}{r^2} \right) \\ -\lambda_r + \lambda_v \frac{v}{r} \\ -\lambda_u \frac{2v}{r} + \lambda_v \frac{u}{r} \end{bmatrix}$$

1.4 Equation de la commande

$$H = 1 + \lambda^T f = 1 + \lambda_r u + \lambda_u \left(\frac{v^2}{r} - \frac{\mu}{r^2} + \frac{T}{m_0 + \dot{m} \times t} \sin(\phi) \right) + \lambda_v \left(-\frac{uv}{r} + \frac{T}{m_0 + \dot{m} \times t} \cos(\phi) \right)$$

$$\frac{\partial H}{\partial \phi} = \lambda_u \left(\frac{T}{m_0 + \dot{m} \times t} \cos(\phi) \right) - \lambda_v \left(\frac{T}{m_0 + \dot{m} \times t} \sin(\phi) \right) = 0$$

$$\frac{\partial H}{\partial \phi} = 0 \Leftrightarrow \lambda_u \cos(\phi) - \lambda_v \sin(\phi) = 0 \Rightarrow \tan(\phi) = \frac{\lambda_u}{\lambda_v}$$

1.5 Condition d'optimalité sur t_f

$$\left[H = 1 + \lambda^T f = 1 + \lambda_r u + \lambda_u \left(\frac{v^2}{r} - \frac{\mu}{r^2} + \frac{T}{m_0 + \dot{m} \times t} \sin(\phi) \right) + \lambda_v \left(-\frac{uv}{r} + \frac{T}{m_0 + \dot{m} \times t} \cos(\phi) \right) \right]_{t_j} = 0$$

Cette condition peut être remplacée par la condition équivalente à $t_0 = 0$:

$$[\lambda^T \times \lambda]_{t_0} = 1$$

1.6 Formulation du problème aux deux bouts

Inconnues à $t = t_0 = 0$: $\lambda(t_0)^T = [\lambda_r \ \lambda_u \ \lambda_v]_{t_0}$

Inconnue à $t = t_f$: t_f Système d'équations à résoudre:

$$g(\lambda_{r0}, \lambda_{u0}, \lambda_{v0}, t_f) = \begin{bmatrix} r(t_f) - r_f \\ u(t_f) \\ v(t_f) - \sqrt{\frac{\mu}{r_f}} \\ [1 + \lambda^T f]_{t_f} \end{bmatrix} = 0$$

2 Implementation

Algorithm 1 Problem data declaration

Data:

- Initial Conditions:

- $AU = 149597870690$
- $r_0 = AU$
- $u_0 = 0$
- $v_0 = \sqrt{\frac{\mu_{body}}{r_0}}$
- $m_0 = 1000$

- Final Conditions:

- $r_f = 1.5 \times AU$
- $u_f = 0$
- $v_f = \sqrt{\frac{\mu_{body}}{r_f}}$

- Power:

- Set T to an array containing values from 0.1 to 0.6 with a step size of 0.1.

- Earth gravity

- $g_0 = 9.80665$

- Specific motor impulse

- $Isp = 3000$

- sun's gravitational constant

- $\mu_{body} = 1.32712440018e + 20$
-

2.1 Problem Data declaration

In this code, we have to normalize the data due to the problem of orders of magnitude. This allows us to make the resolution easier and more accurate for the solver.

Algorithm 2 Problem data declaration

Normalized unit:

- Unit:

- $DU = r_0;$
 - $VU = v_0;$
 - $MU = m_0;$
 - $TU = \frac{DU}{VU};$
 - $FU = \frac{MU \times DU}{TU^2};$
-

2.2 System Dynamics Resolution function

Algorithm 3 Dynamical model of a spacecraft

Definition of the struct:

$$\begin{aligned}
 \text{param.DU} &= DU; \\
 \text{param.VU} &= VU; \\
 \text{param.MU} &= MU; \\
 \text{param.TU} &= TU; \\
 \text{param.FU} &= FU; \\
 \text{param.}\mu_{\text{body}} &= \frac{\mu_{\text{body}}}{\text{param.DU}^3 \times \text{param.TU}^2}; \\
 \text{param.T} &= \frac{T(1)}{\text{param.FU}}; \\
 \text{param.}g0_{\text{Isp}} &= \frac{g0 \times Isp}{\text{param.VU}}; \\
 \text{param.}m0 &= \frac{m0}{\text{param.MU}}; \\
 \text{param.}t0 &= 0; \\
 \text{param.}x_{t0} &= \begin{bmatrix} \frac{r0}{\text{param.DU}} \\ \frac{u0}{\text{param.VU}} \\ \frac{v0}{\text{param.VU}} \end{bmatrix}; \\
 \text{param.}x_{tf} &= \begin{bmatrix} \frac{rf}{\text{param.DU}} \\ \frac{uf}{\text{param.VU}} \\ \frac{vf}{\text{param.VU}} \end{bmatrix};
 \end{aligned}$$

Algorithm 4 Function dynpol

Input:

- t : A given time step

- $x = \begin{bmatrix} r \\ u \\ v \\ \lambda_r \\ \lambda_u \\ \lambda_v \end{bmatrix}$: the state of the dynamic system vector

function *dynpol*(t, x)

$$\mu = \text{param}.\mu_{\text{body}}$$

$$T = \text{param}.T;$$

$$g0_{\text{isp}} = \text{param}.g0_{\text{isp}}$$

$$m0 = \text{param}.m0;$$

$$t0 = \text{param}.t0;$$

$$dm = -\frac{T}{g0_{\text{isp}}}$$

$$\phi = \arctan\left(\frac{x(5)}{x(6)}\right)$$

$$dx = x;$$

$$dx(1) = x(2);$$

$$dx(2) = \frac{x(3)^2}{x(1)} - \frac{\mu}{x(1)^2} + \frac{T}{m0+dm \times t} \times \sin(\phi)$$

$$dx(3) = -\frac{x(2) \times x(3)}{x(1)} + \frac{T}{m0+dm \times t} \times \cos(\phi)$$

$$dx(4) = -x(5) \times \left(-\frac{x(3)^2}{x(1)^2} + 2 \times \frac{\mu}{x(1)^3}\right) - x(6) \times \frac{x(2) \times x(3)}{x(1)^2}$$

$$dx(5) = -x(4) + x(6) \times \frac{x(3)}{x(1)};$$

$$dx(6) = -x(5) \times \left(2 \times \frac{x(3)}{x(1)}\right) + x(6) \times \frac{x(2)}{x(1)};$$

end function

Algorithm 5 Function `gnultmin`

Input:

- $p = \begin{bmatrix} t_f \\ \lambda_{r0} \\ \lambda_{u0} \\ \lambda_{v0} \end{bmatrix}$: the state of the dynamic system vector

```
function GNMT( $p$ )  
   $t0 = \text{param}.t0$ ;  
   $r0 = \text{param}.x_{t0}(1)$ ;  
   $u0 = \text{param}.x_{t0}(2)$ ;  
   $v0 = \text{param}.x_{t0}(3)$ ;  
   $rf = \text{param}.x_{tf}(1)$ ;  
   $uf = \text{param}.x_{tf}(2)$ ;  
   $vf = \text{param}.x_{tf}(3)$ ;  
   $y0 = [r0 \ u0 \ v0 \ p(2) \ p(3) \ p(4)]$ ;  
   $tf = p(1)$ ;  
   $atol = 1e - 10$ ;  
   $rtol = 1e - 10$ ;  
   $y = \text{ode}('rk', y0, t0, tf, \text{dynpol}, atol, rtol)$ ;  
   $gnmt = p$ ;  
   $gnmt(1) = y(1) - rf$ ;  
   $gnmt(2) = y(2) - uf$ ;  
   $gnmt(3) = y(3) - \sqrt{\text{param}.\mu_{\text{body}}/rf}$ ;  
   $gnmt(4) = p(2)^2 + p(3)^2 + p(4)^2 - 1$ ;  
end function
```

The function `gnultmin()` takes p as a parameter and returns the column vector $gnmt$.

Absolute and relative tolerances of 10^{-10} have been chosen for solving the differential equation using the function `ode()`. If the order of magnitude of the relative tolerance is smaller than 10^{-10} , Scilab displays a warning message and increases this tolerance to have an order of magnitude of 10^{-10} .

We aim to achieve better accuracy than that of the solver.

Algorithm 6 Control History Calculation

```
1: for  $i = 1$  to 6 do
2:    $param.T \leftarrow \frac{T(i)}{param.FU}$ 
3:    $[x, v, info] \leftarrow fsolve(p_0, gnultmin)$ 
4:    $disp(info)$ 
5:    $disp(v)$ 
6:    $InitialCond \leftarrow [param.x\_t0(1); param.x\_t0(2); param.x\_t0(3); x(2); x(3); x(4)]$ 
7:    $t \leftarrow 0 : 0.01 : x(1)$ 
8:    $sol \leftarrow ode(InitialCond, param.t0, t, dynpol)$ 
9:    $timeInDays \leftarrow t \times \frac{param.TU}{86400}$ 
10:   $AngleInDegrees \leftarrow atan(sol(5, :), sol(6, :)) \times \frac{360}{2\pi}$ 
11:   $figure$ 
12:   $plot(timeInDays, AngleInDegrees)$ 
13:   $xlabel('Time(days)')$ 
14:   $ylabel('Controlindeg')$ 
15:   $powerInNewton \leftarrow param.T \times param.FU$ 
16:   $xgrid$ 
17:   $h \leftarrow gca()$ 
18:   $h.background \leftarrow color('white')$ 
19:   $title('Controlhistoryfor' + string(powerInNewton) + ' N')$ 
20: end for
```

Each thrust (in Newtons) is contained in T . We proceed with increasing thrusts, starting with the lowest one (here 0.1), so the thrust duration decreases. The very first time the function $gnultmin()$ is passed as a parameter to the function $fsolve()$, i.e., to calculate the trajectory with the first thrust, we use p_0 for the initialization of $gnultmin()$. The result of the first use of $fsolve()$ called p_1 will serve for the second time when we pass $gnultmin()$ as a parameter to $fsolve()$, hence for calculating the trajectory with the second thrust. Thus, for each thrust except the first one, we use the result of $fsolve()$ from the previous thrust. With p_0 , we can then obtain p_i for all $i \in [1; 6]$.
